ABSTRACT

This article re-examines the practitioner profile and organizational-culture findings reported in a 2016 doctoral dissertation on the Philippine real estate industry. The source study used a descriptive design and surveyed 239 licensed real estate practitioners in Luzon who were affiliated with professional organizations. Organizational culture was measured across ethical, innovative, customer-responsive, and spiritual dimensions using a four-point agreement scale. The respondent profile was predominantly male (68%), married (96%), college educated (92%), and composed largely of brokers (68%); 57% reported one to five years of service. Across the four culture dimensions, innovation produced the highest mean (3.71), followed by customer responsiveness (3.61), ethical culture (3.59), and spiritual culture (3.54). Although the dissertation described workplace spirituality as relatively weak, the reported mean still falls within the source study's "Strongly Agree" category, indicating that the weakness is comparative rather than absolute. Item-level patterns also reveal a contrast between strong communication of

ethical expectations and weaker use of visible rewards and punishments, while the spiritual dimension combines a strong search for involvement with comparatively lower community connection and work-life value integration. The secondary analysis suggests a broadly positive but only modestly differentiated cultural profile and highlights the need to distinguish relative ranking from low absolute endorsement.

Keywords: *real estate practitioners, organizational culture, innovation, customer responsiveness, ethical culture, workplace spirituality, Philippines*

INTRODUCTION

Organizational culture influences how professionals interpret expectations, respond to clients, make decisions, and understand their relationship with the organizations and networks in which they operate. In real estate, those cultural patterns are especially relevant because practitioners frequently work with substantial autonomy, manage information asymmetries between buyers and sellers, and depend on reputation, referrals, and professional credibility. The source dissertation approached the real estate industry through four dimensions adapted from Robbins and Coulter: ethical culture, innovative culture, customer-responsive culture, and spiritual culture.

The purpose of this article is not to reproduce the dissertation as a whole. Instead, it isolates two linked questions: Who were the licensed practitioners represented in the source study, and what cultural profile emerged from their responses? This focused re-analysis

is useful because the dissertation combined professional demographics, policy concerns, and societal contributions in one broad study. Treating the practitioner profile and culture scores as a standalone article allows the cultural findings to be examined with greater attention to relative differences, item- level contrasts, and interpretive limits.

Method

The source study employed a descriptive research design. Survey respondents were licensed real estate practitioners - brokers, appraisers, consultants, or practitioners holding overlapping roles - in the Luzon area. Participants were affiliated with organizations identified in the dissertation, including the Philippine Association of Realtors Board, National Real Estate Appraisers, Mexico Real Estate Brokers, City of San Fernando Real Estate Brokers, and Philippine Real Estate Services Practitioners. The study was conducted in Pasig and Pampanga settings associated with practitioner meetings and activities.

The dissertation reports 239 survey respondents in its socio-demographic profile table. A questionnaire was used to identify organizational culture, followed by a short interview for policy implications. Frequency counts, percentage distributions, means, and rankings were used. The culture items were interpreted using the source scale: 3.50-4.00 = Strongly Agree; 2.50-3.49 = Agree; 1.50-2.49 = Disagree; and 1.00-1.49 = Strongly Disagree.

Results

Practitioner Profile

Characteristic Largest category Frequency / percentage

Sex Male 163 / 68%

Age 31-40 years 86 / 36%

Civil status Married 230 / 96%

Educational attainment College graduate 219 / 92%

Professional role Broker 163 / 68%

Length of service 1-5 years 138 / 57%

The profile describes a practitioner group concentrated in active working ages and dominated by licensed brokers. A substantial proportion also held overlapping professional roles, including broker-appraiser combinations. The source table reports 57% of respondents with one to five years of service. A later summary page contains the typographical form “567%”; this article uses the 57% value from the primary profile table and explicitly notes the discrepancy rather than silently treating the summary text as correct.

Four Dimensions of Organizational Culture

Culture dimension Mean Source interpretation Relative position

Innovative culture 3.71 Strongly Agree 1

Customer-responsive culture 3.61 Strongly Agree 2

Ethical culture 3.59 Strongly Agree 3

Spiritual culture 3.54 Strongly Agree 4

All four dimension means fall inside the source study's highest interpretive category. The difference between the highest and lowest dimension means is only 0.17 on a four-point scale. This relatively narrow spread matters. It

indicates that innovation was the strongest dimension in rank order, but it does not support treating the other dimensions as absent or rejected.

Within ethical culture, communicating ethical expectations received the highest item mean (3.92), while visible reward for ethical acts and punishment received the lowest (3.03). The pattern suggests that norms and expectations were strongly expressed, but formal reinforcement through rewards and sanctions was less strongly endorsed. The dissertation linked ethical expectations to the professionalization environment created by the Real Estate Service Act and its implementing rules.

Innovative culture had the highest overall dimension mean. The strongest innovative item was having enough time to elaborate new ideas before taking action (3.78). Independent initiative was also highly rated (3.77). The source discussion connected innovation with negotiation, technology use, risk taking, and the independence commonly experienced by practitioners.

Customer responsiveness was also strongly endorsed. Training customer-service personnel on product knowledge, active listening, patience, and emotional display received a mean of 3.66. Job design, empowerment, socialization, and customer-focused leadership were likewise rated in the strongly agree range. The dissertation interpreted this orientation as a potential competitive advantage because real estate transactions depend heavily on trust, referrals, and word-of-mouth recommendations.

The spiritual dimension requires careful reading. Practitioners strongly endorsed looking for involvement

and connection (3.89) and seeking meaning and purpose in work (3.79). At the same time, desire to connect with other human beings and be part of the community received 3.07, while integration of personal-life values with professional life received 3.26. Thus the lower dimension mean appears to come from unevenness within workplace spirituality rather than a uniformly negative spiritual culture.

Discussion

The central finding is a culture profile with broad positive endorsement and modest relative differentiation. Innovation is the leading dimension, but customer responsiveness, ethics, and spirituality remain close behind. For editorial and scholarly purposes, it is therefore more precise to describe spirituality as the lowest-ranked dimension than to call it simply weak. The source's own scoring system places 3.54 in the "Strongly Agree" interval.

The item-level results also show that organizational culture is not a single uniform phenomenon. Ethical expectations can be well communicated even when formal reward-and-punishment systems are less visible. Practitioners can report strong purpose and involvement while simultaneously reporting weaker community connection. A culture score can therefore conceal internal tensions that become visible only when individual items are examined.

The practitioner profile also provides context for the culture results. Brokers represented the largest professional group, many respondents had only one to five years of service, and overlapping roles were

common. These characteristics may help explain the emphasis on autonomy, negotiation, client responsiveness, and innovation. However, the source study did not test statistical relationships between demographic variables and culture scores. Any such explanation remains interpretive rather than causal.

LIMITATIONS

The article is based entirely on the dissertation's reported tables and narrative. It does not have access to raw respondent-level data and therefore cannot verify scale reliability, conduct inferential tests, or estimate associations between profile variables and culture dimensions. The source used organizational affiliations and selected Luzon settings rather than a documented probability sample of all Philippine real estate practitioners. Several minor inconsistencies occur between narrative text and tables; where a conflict is visible, this article prioritizes the clearly labeled source table and identifies the issue when material.

CONCLUSION

The 2016 dissertation data portray a licensed real estate practitioner community that strongly endorsed all four measured cultural dimensions. Innovation ranked first, followed by customer responsiveness, ethical culture, and spirituality. The most useful secondary insight is that relative rank should not be confused with absolute weakness: the lowest dimension still met the source's highest agreement category. Future work using the dataset, if raw data remain available, could test whether culture scores differ by professional role, length of

service, age group, or organizational affiliation. Without those raw data, the present article is appropriately limited to descriptive secondary analysis.
